

## I. Introduction

### A. Background of the Study

Information technology is very vital in providing better health care in the country. Nowadays, more and more hospitals and health institutions use information systems to deliver better and faster health administration. The use of these systems for storing electronic records has become a typical practice. Large amounts of data are collected routinely by health and social care systems in order to support clinical management and patient care. Usage of this data has enormous potential in health-related research, quality improvement, service planning and enhanced clinical decision-making [1].

Data warehouses are large and specialized form of database used to store vast amount of data that can be used in analyzing health information. Its main goal is to formulate queries, reports and complex analysis. The data warehousing technology is hailed to provide effective information usage and knowledge discovery in databases [2].

With the advent of the data warehouse, the effort of separately searching at different databases will no longer be needed. Data warehouses can perform all of the complex queries and data mining that regular databases can [3].

Web-mapping has become one of the fastest trends nowadays when it comes to displaying data integrated into a map. There are already a number of free Web-mapping services available like the Google Maps which is the most commonly used free web-mapping service in the internet. Google provides an API for the Google Maps Web Application, a function that allows one to integrate Google Maps into their own application and websites [4].

Mapping of statistical data provides a great way of visualizing trends and relationships. Because data warehouses are mainly created for data analysis, creating a data warehouse with a mapping functionality shows great potential in improving visualization of collected information.

The National Telehealth Center (NThC) is a research unit at the University of the Philippines Manila committed to develop technology for better health care [5]. Under their Knowledge Base Module are systems like Community Health Information Tracking System for dental health care and diseases record, and Nearest Hospital Search and Inquiry System for hospital and doctors' records. On the other hand, the Integrated Surgery Information System is designed for injury and surgery records. Previous special problems of alumni's from the University of the Philippines-Manila such as the Child Immunization Database and Community –Based Nutrition Monitoring System are designed to store immunization and nutrition records respectively.

## B. Statement of the Problem

Different information systems for vast kinds of data are almost everywhere in the Philippines, most of which are used in the medical field. These databases proved to be helpful in aiding the health professionals in retrieving necessary health information. Nonetheless, there is a dearth in organization and management of such systems. Data are highly diverse and widely scattered across hundreds of databases and thus presents difficulty to health professionals in exploiting collected data.

Most of the existing health-related information systems are only made for a specific purpose or area of study, thus, gathering of information for areas of interest at once will take a lot of effort. An individual will need to check out different sources relevant to the problem at hand. Aside from checking different sources, data are also presented in various formats. A good illustration of data in different formats would be the information regarding location. For example, one system stores their regions as the common format, Region I, Region II, Region III, etc. Another system would use the full name of the regions and the other one a combination of both. Extra effort must be exerted to interpret the gathered data and make meaningful integrated reports.

Statistical reports are usually generated on different systems. However, most of them are displayed in tabular format wherein analyzing data relationships and trends is not very user-friendly. Providing graphical and spatiotemporal representation of statistical information can

help them investigate correlations of different data easier and faster. A system called Telehealth Geographical Information System was previously created to provide map representations for statistical data. However, the source systems included in the Telehealth Knowledge Base's Module have different location formats than that of the TGIS and must be transformed first into a standard format.

### C. Objectives of the Study

The purpose of this study is to create a data warehouse that collects data from five different databases namely Nearest Hospital Search Information System (NHSIS), Community-Based Nutrition Monitoring System (NMS), Child Immunization Database System (CIDS), Integrated Surgery Information System (ISIS) and Community Health Information Tracking System (CHITS). The system implements data transformations to make its records follow a standard location format and adapt the existing location records provided by the Telehealth Geographical Information System and integrate its mapping functionality.

The system has the following functionalities:

- A. Allows registered users such as NThC employees and researchers to:
  - a. Search for hospitals and other health institutions using name, region, city, type, facility and quantity as search parameters.
  - b. View hospitals and other health institutions' basic information, list of doctors and list of facilities.
  - c. Search for doctors using doctor name, region, city, specialty and schedule as search parameters.
  - d. View a doctor's basic information and his/her schedule on different hospitals.
  - e. Search for the following immunization reports given region, city and time span as query parameters:
    - e.i. Fully Immunized Child Rate

- e.ii. Accomplishment Report Per Schedule
    - e.iii. Accomplishment Report Per Vaccines
  - f. Search for the following nutrition reports given region, city and time span as query parameters:
    - f.i. Food Supplementation Program
    - f.ii. Nutritional Status Report
    - f.iii. Vitamin A Supplementation Program
    - f.iv. Iron and Iodine Supplementation Program
  - g. Search for disease frequency per age and gender given disease name, region, city and time span as query parameters
  - h. Search for dental health reports given region, city and time span as query parameters.
  - i. Search for injury frequency per age and gender given injury mechanism, region, city and time span as query parameters
  - j. Search for the following surgery statistical reports using time span as input:
    - j.i. Per Outcome
    - j.ii. Per Classification
    - j.iii. Per Operation Type
  - k. View statistical reports in graphical representation
  - l. View hospitals and statistical reports in map representation via the adapted mapping functionality of the TGIS.
  - m. Update their account information.
- B. Allows guest users to:

- a. Search for hospitals and other health institutions using name, region, city, type, facility and quantity as search parameters.
- b. View hospitals and other health institutions' basic information, list of doctors and list of facilities.
- c. Search for doctors using doctor name, region, city, specialty and schedule as search parameters.
- d. View a doctor's basic information and his/her schedule on different hospitals.
- e. View search results in an online interactive map via the adapted mapping functionality of TGIS

C. Allows System Administrators to:

- a. Update the data warehouse manually.
- b. Add, edit and delete a user account.

#### D. Significance of the Study

The Nearest Hospital Search and Inquiry System provides information regarding hospitals, doctors and facilities. The Integrated Surgery Information System provides information regarding injury and accident cases. CHITS is capable of generating reports on diseases and dental health, etc. The Community-Based Nutrition Monitoring System generates statistical reports with regards to malnourishment and lack of food supplements. CIDS outputs statistical reports on the frequency of child immunization.

The integration of all these various information in a data warehouse provides a one-stop shop of facts and figures for health professionals. The system allows users to immediately see diverse information from different sources in a single location, saving them time and effort of going through different information systems. Aside from that, the Extract-Transform-Load process of a data warehouse integrates and presents the source data in a standard manner. Reports are consistent and easier to analyze. Aside from the usual tables, statistical reports have alternate

representations via graphs and an interactive map. This provides better data visualization and analysis of data trends and relationships for decisioning support.

## E. Scope and Limitations

- a. The system only includes data from the different databases of the Telehealth's Knowledge Base Module (e.g. NHSIS, NMS, CIDS, ISIS, and CHITS). Data are limited to what these source operational systems can provide.
- b. Only the data needed for generating the reports of interest are stored in the data warehouse. Patients' personal information such as names or addresses are ignored.
- c. The system administrator must update the data warehouse regularly. Data is only valid up to the last update made by the system administrator.
- d. The system only uses the full-refresh update – the data warehouse is emptied and a new copy of the data marts are inserted for every update.
- e. Aside from the user account management, the system doesn't have any add, edit and delete functionality. The information stored in the data warehouse is read-only because it is solely created for searching data.
- f. The mapping functionality is limited to what the Google Maps API can provide. The system must also abide by its terms and conditions.
  - f.i. A system that uses the API is not allowed for commercial use.
  - f.ii. The free web-mapping functionality is limited to 25,000 views only.

## F. Assumptions

- a. The operational databases are uploaded on the same server as the Telehealth Knowledge Base and the system will have access to their database tables.

- b. CHITS is actually decentralized. It is assumed that CHITS has a main central repository for all of its community data and the Telehealth Knowledge Base only accesses that repository.
- c. The operational databases are populated and data stored on them are correct. The system assumes that the source operational databases had already done the validation of its records.

## II. Review of Related Literatures

A data warehouse is a relational database that is designed for query and analysis rather than for transaction processing. It usually contains historical data derived from transaction data, but it can include data from other sources. It separates analysis workload from transaction workload and enables an organization to consolidate data from several sources [1]. Different from classical operational databases, a data warehouse is a subject-oriented, integrated, non-volatile and time variant collection of data in support of management's decisions [6].

Nowadays, data warehousing serves as key technology for the manipulation of huge amounts of data available in many organizations or field of studies. In the field of translational medicine, the tranSMART system is found to be widely used across multiple therapeutic areas within the pharmaceutical companies of Johnson and Johnson. The system allows clinicians, translational scientists and discovery biologists to interrogate aligned phenotype/genotype data to enable better clinical trial design or to stratify disease into molecular subtypes with great efficiency [7].

Data warehouses are also proved to be useful on the field of bioinformatics. Fischer et.al created the data warehouse system DWARF to integrate data on sequence, structure, and functional annotation for protein fold families. It has been designed for constructing databases of large structurally related protein families and for evaluating their sequence-structure-function relationships by a systematic analysis of sequence, structure and functional annotation. It was applied to predict biochemical properties from sequence, and serves as a valuable tool for protein engineering [8]. In the Uppsala University of Sweden, Ameur et. Al. developed the Linnaeus Centre for Bioinformatics Data Warehouse ((LCB-DW)). It is a web-based infrastructure for reliable and secure microarray gene expression data management and analysis that provides an online service for the scientific community. It helps facilitate management and analysis of two-channel microarray data, and to help non-experts to keep-up with developments in the field of data analysis by continuously integrating new tools and new sources of biological information. [9]

For the field of health informatics, data warehouses are also widely used. Ford et.al established the SAIL databank, a national databank of anonymised person-based records, so that the data are available for research and evaluation whilst meeting the requirements of Information Governance of UK. [3] To improve the quality of care to patients with Parkinson's disease in the Pacific Northwest, Swarztrauber et.al established the use of their administrative database, Pacific Northwest Veterans Health Administration (VHA) Data Warehouse [10].

Data warehousing usually adapts to store and manipulate numerical data. However it is not convenient to query, analyze and visualize spatial geographical data. The integration of a

Geographic Information Systems in a data warehouse can help solve this problem since GIS can provide mapping functionalities for spatiotemporal evaluation of information. In a study done by Cooper et.al last 2008, the use of GIS in the analyses of telehealth data provided a timely and unique description of the evolution of a national influenza outbreak [11].

There are significant barriers to conducting community health assessment in developing countries. These include high cost of computing resources and the lack of computing skills necessary to support such an assessment. At the University of Pittsburgh, Parmanto et.al developed the Spatial OLAP (On-Line Analytical Processing) Visualization and Analysis Tool (SOVAT) for performing community health assessment. SOVAT combines Geographic Information System (GIS) technology along with an advanced multidimensional data warehouse structure to facilitate analysis of large, disparate health, environmental, population, and spatial data. [12]

Web-based Geographical Information Systems provide a real-time and dynamic way to represent disease information on maps. However, data heterogeneities, integration, interoperability, and cartographical representation are still major challenges in the health geographic fields. These challenges cause barriers in extensively sharing health data and restrain the effectiveness in understanding and responding to disease outbreaks. To overcome these challenges, Gao et.al of University of Brunswick, Canada has designed an interoperable service oriented architecture based on Open Geospatial Consortium specifications to share the spatiotemporal disease information [13].

Surveillance of climate-related health vulnerabilities must take into account climate change and population vulnerabilities, their interdependence, as well as their inherent spatial and temporal aspects on several scales, for informed analyses. Currently used technology includes commercial off-the-shelf Geographic Information Systems (GIS) and Database Management Systems with spatial extensions. However, these systems were not designed to support complex, multi-temporal and multi-scale analysis as required above. Bernier et.al developed Spatial On-Line Analytical Processing to investigate and combine climate-related health vulnerability data to facilitate surveillance. [14]

Data warehouses with GIS are not only useful for fields related to health. With the progress of water supply company reform, the enterprise's leaders are eager to optimize productivity by strengthening the information management in order to improve the competition ability. For this reason, Gio and Hao of Wuhan University of Technology proposed to build a data warehouse based on GIS to delineate the area of the distinct difference between supply and sale in lots of water supply companies. [15] In the hydrological industry, Fan et.al recommended the use of a data warehouse to solve the multisource heterogeneous data management issues and achieve a variety of software sharing functions to establish digital platform. [16]

### **III. Theoretical Framework**

#### **A. National Telehealth Center, UP-PGH**

The National Telehealth Center is a research unit at the University of the Philippines Manila committed to develop technology for better health care. Established in June 1998, it

mandates to increase access of Filipinos to health information and service through the use of appropriate technology. The unit envisions healthy citizenry cognizant of their basic human right to health and empowered by information technology. By increasing access to quality health information, the UPM-NThC anticipates civil society contributing to an integrated national health information system founded on data generated by responsible citizens supported by state-of-the-art computer algorithm [5].

The main goal of UPM-NThC is to empower Filipinos to take greater responsibility for their health through the appropriate use of information and communications technology. Riding on a robust and expansive cellular phone network, UPM-NThC develops simple and relevant telehealth applications using free and open source software [5].

## B. Data Warehouse

A data warehouse is a collected view of data, optimized for reporting and analysis. Data from the production databases are copied to the data warehouse so that queries can be performed without altering the performance of the production systems. Basically, it is a summarized copy of transaction and non-transaction data specifically structured for dynamic queries and analytics [17]. Data are organized in such a way that it can be easily analyzed, extracted, synthesized, and otherwise be used for the purposes of further understanding the data.

Data from various online transaction processing (OLTP) applications and other sources is selectively extracted and organized on the data warehouse database for use by analytical applications and user queries. Data warehousing emphasizes the capture of data from diverse sources for useful analysis and access, but does not generally start from the point-of-view of the end user or knowledge worker who may need access to specialized, sometimes local databases. Data warehouse can also be described as subject-oriented, integrated, time-variant, non-updatable collection of data used in support of management decision-making processes. It is consistent in naming conventions, formats, encoding structures, from multiple data sources. It can study trends and changes. It is non-updatable because it is read-only and is only periodically refreshed [18].

## **Components of a Data Warehouse**

A data warehouse has four distinct components namely:

- **Operational Source Systems**

These are the operational systems of record that capture the transactions of the business. The main priorities of the source systems are processing performance and availability. Queries against source systems are narrow, one-record-at-a-time queries that are part of the normal transaction flow and severely restricted in their demands on the operational system. Also, source systems maintain little historical data [19].

- **Data Staging Area**

The data staging area of the data warehouse is both a storage area and a set of processes commonly referred to as ***extract-transformation-load (ETL)***. The data staging area is everything between the operational source systems and the data presentation area. Raw operational data is transformed into a warehouse deliverable fit for user query and consumption. Data staging area is accessible only to skilled professionals for security purposes [19].

Extraction is the first step in the process of getting data into the data warehouse environment. Extracting means reading and understanding the source data and copying the data needed for the data warehouse into the staging area for further manipulation. Once the data is extracted to the staging area, there are numerous potential transformations, such as cleansing the data, combining data from multiple sources, deduplicating data, and assigning warehouse keys. The final step of the ETL process is the loading of data. Loading in the data warehouse environment usually takes the form of presenting the quality-assured dimensional tables to the bulk loading facilities of each data mart. The target data mart must then index the newly arrived data for query performance. When each data mart has been freshly loaded, indexed, supplied with appropriate aggregates, and further quality assured, the user community is notified that the new data has been published [19].

- **Data Presentation**

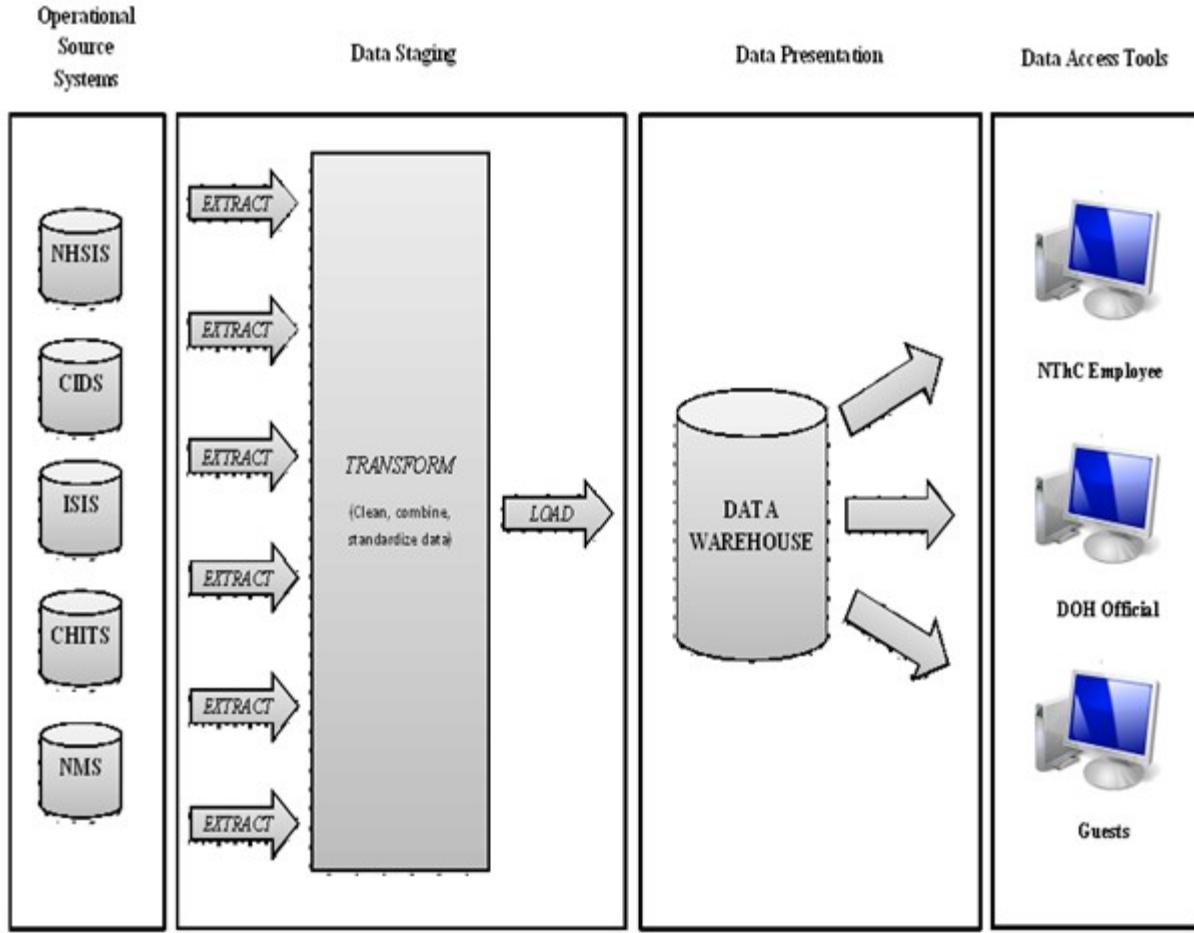

The data presentation area is where data is organized, stored, and made available for direct querying by users, report writers, and other analytical applications. As far as the business community is concerned, the presentation area is the data warehouse itself [19].

- **Data Access Tools**

Data access tools refer to the variety of capabilities that can be provided to business users to leverage the presentation area for analytic decision making. By definition, all data access tools query the data in the data warehouse's presentation area.

The majority of the business user base likely will access the data via prebuilt parameter-driven analytic applications. Some of the more sophisticated data access tools, like modeling or forecasting tools, actually may upload their results back into operational source systems or the staging/presentation areas of the data warehouse [19].

Figure 1 shows the data warehouse components of the Telehealth Knowledge Base. It basically shows the data flow from each component of the data warehouse.

**Figure 1:** Data Warehouse Components, Telehealth Knowledge Base

### Data Warehouse versus Operational Database

An operational database is a database that is designed and optimized to facilitate recording of data. They are OLTP (On-Line Transaction Processing) systems where every transaction has to be recorded, fast. This system is write-optimized, thus, analysis query takes a lot of time on such a system. [20]

A Data Warehouse on the other hand, is a database that is *designed* for facilitating querying and analysis. It is designed to respond to analysis questions that are critical to the field of interest. Often designed as OLAP (On-Line Analytical Processing) systems, these databases

contain read-only data that can be queried and analysed far more efficiently as compared to your regular OLTP application databases. Data warehouses are designed to be read-optimized. [20]

## **OLAP versus OLTP**

On-Line Transactional Processing (OLTP) is described as a category of software technology characterized by a large number of short on-line transactions such as insert, update and delete. Its main emphasis is put on very fast query processing, maintaining data integrity in multi-access environments and an effectiveness measured by number of transactions per second. [21]

On-Line Analytical Processing (OLAP) is described as a category of software technology that characterized by relatively low volume of transactions. Queries are often very complex and involve aggregation. OLAP focuses on storing historical data, mostly on multidimensional schemas such as star and snowflake schemas. [21]

## **C. Dimensional Modeling**

Dimensional modeling is a technique for conceptualizing and visualizing data models as a set of measures that are described by common aspects of the business. Dimensional modeling is comprised of fact and dimensions. A fact is a collection of related data items, consisting of measures. It is a focus of interest for the decision making process. It is the primary table where data are stored. Dimensions, on the other hand are parameters over which analysis of facts are performed. They are the integral companions of the fact table. One example of a multidimensional modeling schema is the snowflake schema in which the dimensional tables from a star schema are organized into a hierarchy by normalizing them. Some installations are normalizing DW up to third normal form; so that they can access the DW efficiently .i.e. dimension table hierarchies are broken into simpler table. [22]

Figure 2 shows the basic form of a snowflake schema.

**Figure 2:** Basic Structure, Snowflake Schema

#### D. Geographic Information System

GIS is a technological field that incorporates geographical features with tabular data in order to map, analyze, and assess real-world problems. The key word to this technology is Geography – this means that some portion of the data is spatial, in other words, data that is in some way referenced to locations on the earth. Coupled with this data is usually tabular data known as attribute data. Attribute data can be generally defined as additional information about each of the spatial features. An example of this would be schools. The actual location of the schools is the spatial data. Additional data such as the school name, level of education taught, student capacity would make up the attribute data. It is the partnership of these two data types that enables GIS to be such an effective problem solving tool through spatial analysis [23].

GIS operates on many levels. On the most basic level, GIS is used as computer cartography, i.e. mapping. The real power in GIS is through using spatial and statistical methods to analyze attribute and geographic information. The end result of the analysis can be derivative information, interpolated information or prioritized information [23].

#### E. Google Maps API

Google Maps API is a Google service that offers powerful, user-friendly mapping technology and local business information which includes driving directions, contact information and business locations. It has the following unique features [24]:

- Integrated search results – location and contact information integrated on the map.
- Draggable maps – click and drag to view adjacent areas immediately
- Satellite imagery – views a satellite image that can be zoomed

- Terrain maps – view physical features with elevation shading
- Street view – navigate within street-level imagery
- Keyboard shortcut – pan left, right, up and down with the arrow keys; pan wider with the Page Up, Page Down, Home and End keys; zoom in and out with the plus (+) and minus (-) keys.
- Double-click to zoom functionality – double left-click to zoom-in, and double right click to zoom out
- Scroll wheel zooming – use the mouse scroll wheel to zoom in and out

#### **F. Community Health Information Tracking System (CHITS)**

The Community Health Information Tracking System is a free and open source software electronic health record system for local government health centers in the Philippines. A grant from the International Development Research Centre of Canada was given to Dr. Herman Tolentino for its creation. CHITS has been expanding to rural health units around the country since 2004. The UP Manila – National Telehealth Center is in charge of the CHITS management. It is a part of the “Using Computers and Cellphones to Improve Local Health Information Systems” program [25].

#### **G. Nearest Hospital Search and Inquiry System (NHSIS)**

The Nearest Hospital Search and Inquiry System, a BS Computer Science Special Problem (SP) by Meybel Martirez, is a web-based application that generates clinical data by registered hospitals. Registered and general users could issue their queries on the hospital nearest to their location, doctors' schedule of activities and the list of available facilities and specialties. Its SMS application determines the hospital they need using the categories specified. Reports are sent back to the mobile users as well as the correct message format for errors in message [26].

#### **H. Child Immunization Database System (CIDS)**

The Child Immunization Database System, a BS Computer Science Special Problem (SP) by Apple Peach Coloyan, is a web-based application for immunization records from the Department of Health's Under Five Clinic Growth Chart. It generates summary reports with respect to immunization of Under Five Clinic patients. It is capable of sending SMS messages on a child's follow up reminder to parents, and SMS messages on a child's follow up schedule upon the parent's query. The system may be used as an application for maintaining immunization records and as decision support system [27].

#### **I. Integrated Surgery Information System (ISIS) Database, UP-PGH**

The Integrated Surgical Information System (ISIS), created by Dra. Marie Carmela Lapitan, is a project of the UPCM Medical Informatics Unit that holds relevant information on surgical cases at the Philippine General Hospital. It stores records of patients and surgery and injury (specifically from the trauma ward) data of the surgery department. The database is used by the Patient Registry System and it is accessible to the doctors and selected personnel of the Department of Surgery [28].

#### **J. Community-Based Nutrition Monitoring System (NMS)**

The Community-Based Nutrition Monitoring System, created by Regina Rayos for her Special Problem (SP), is an information system to generate an integrated picture of the nutritious condition of a community for local decision-makers on a regular basis. Community-based nutrition monitoring is an extension of international nutrition surveillance and national nutrition monitoring work to the community level where much of the substantive nutrition activity happens. It represents a constructive integration of familiar concepts related to needs assessment, evaluation and program management information systems [29].

#### **K. Telehealth Geographic Information System (TGIS)**

The Telehealth Geographic Information System is a system for mapping hospitals and statistical reports. It accesses the related clinical and geographical data stored in the Nearest

Hospital Search and Inquiry System database. It uses the data obtained to translate the results of the query parameters and display relevant information in a map. [30]. It was created by Jennifer Ong for her Special Problem.

## IV. Design and Implementation

### A. Context Diagram

Figure 3 shows the context diagram of all the users interacting with the Telehealth Knowledge Base. The system is divided into four main groups namely: the external databases, the System Administrator, NThC / DOH employee and the unregistered users.

**Figure 3:** Context Diagram, Telehealth Knowledge Base

## B. Data Flow Diagrams

Figure 4 shows the Top-Level Data Flow Diagram of the system. The system will implement four major processes: (1) Login, (2) Search, (3) View, (4) Manage system.

**Figure 4:** Top-level Data Flow Diagram, Telehealth Knowledge Base

Figure 5 shows the sub-explosion of the search process. The search criteria can either be hospitals, facilities, nutritional information, immunization information, injury and surgery data, etc. After entering the search criteria, the system mines through the data warehouse for records that match the given parameters.

**Figure 5:** Sub-explosion of 2.0 Search

Shown in Figure 6 is the sub-explosion of the View process. After returning records that match the search parameters inputted by the users, the data warehouse returns results that are displayed using tables and lists. The user can also choose to view the results in graphs and map.

**Figure 6:** Sub-explosion of 3.0 View

**Figure 7:** Sub-explosion of 3.1 View Results

Figure 8 shows the sub-explosion of Manage System. The entire system is managed by the system administrator. The system administrator is also responsible for updating the records of the data warehouse.

**Figure 8:** Sub-explosion of 4.0 Manage System

**Figure 9:** Sub-explosion of 4.1 Manage Map Coordinates

**Figure 10:** Sub-explosion of 4.2 Manage User Accounts

**Figure 11:** Sub-explosion of 4.3 Update Data Warehouse

Figure 11 shows the sub-explosion of the Update Data Warehouse process. The system first extracts data from the five databases using SQL queries. The extracted data are then filtered –the data of interest are gathered and the rest are ignored. Data are then transformed to a standardized format to fit the database structure of the Knowledge Base.

## C. Entity-Relationship Diagrams

**Figure 12:** Entity Relationship Diagram, Telehealth Knowledge Base

Figure 12 shows the schema of the Telehealth Knowledge Base. Because the system is only interested on read-only data, most of its tables are denormalized to reduce the SQL JOINS that it will use for faster querying.

## D. Data Dictionary

The Telehealth Knowledge Base will have the following tables in its database.

### User

| Field         | Type        | Definition                             |
|---------------|-------------|--|
| user_ID       | int         | Unique attribute that defines the user |
| user_name     | Varchar(15) | Specifies the user's login name        |
| user_password | Varchar(15) | Specifies the user's password          |
| User_type     | Varchar(10) | Specifies the type of user             |
| User_FName    | Varchar(30) | Specifies the user's first name        |
| User_LName    | Varchar(50) | Specifies the user's last name         |
| Email         | Varchar(50) | User's email address                   |

### Region

| Field | Type | Definition |
|-------|------|------------|
|       |      |            |

|               |             |                                   |
|---------------|-------------|-----------------------------------|
| regionID      | Int(5)      | Primary key                       |
| regionName    | Varchar(50) | Defines the Region name           |
| commonName    | Varchar(50) | Defines the regions other names   |
| coordinatesID | Varchar(15) | Defines the geocode of the region |
| Sort num      | Int(11)     | Defines the order of a region     |

## Province

| Field        | Type        | Definition         |
|--------------|-------------|--------------------|
| provinceID   | int         | Primary key        |
| regionID     | int         | Region Foreign Key |
| coordinates  | int         | Coordinates        |
| provinceName | Varchar(50) | Name of province   |

## Hospital

| Field      | Type        | Definition                      |
|------------|-------------|---------------------------------|
| HCode      | int         | Hospital Code                   |
| HName      | Varchar(50) | Complete Name of the Hospital   |
| HSyno      | Varchar(30) | Synonymous name of the hospital |
| telNo      | Varchar(20) | Contact Number of the hospital  |
| Street     | Varchar(50) | Street Name                     |
| City       | Varchar(15) | City                            |
| provinceID | Varchar(15) | Province Foreign Key            |
| regionID   | Varchar(15) | Region Foreign Key              |
| Longitude  | float       | Longitude coordinate            |
| Latitude   | float       | Latitude coordinate             |

## Doctor

| Field                 | Type        | Definition                        |
|-----------------------|-------------|-----------------------------------|
| doctorID              | Int(11)     | Primary Key                       |
| HCode                 | Int(11)     | Hospital Foreign Key              |
| specialty name        | Int(11)     | Specialty Foreign Key             |
| Specialty description | Varchar(50) | Description of doctor's specialty |
| doctor sex            | Varchar(6)  | Sex of Doctor                     |

| iodine_given  | varchar(100)   |                              |
| status_food   | varchar(100)   |                              |
| City          | varchar(100)   | City                         |
| Region        | varchar(100)   | Region                       |

## Surgery\_Data

| Field      | Type    | Definition  |
|------------|---------|-------------|
| surgery_id | int(11) | Primary Key |

|                |             |                                      |
|----------------|-------------|--------------------------------------|
|                |             |                                      |
| start_date     | date        | First date after surgery             |
| end_date       | date        | Last date of recovery                |
| operation_date | date        | Date of operation procedure          |
| classification | varchar(30) | Classification of surgery            |
| admission_opd  | varchar(15) | Whether a patient is admitted or not |
| outcome        | varchar(20) | Outcome of surgery                   |
| age            | int(11)     | Patient age                          |
| gender         | char(1)     | Patient gender                       |
| operation_type | varchar(30) | Operaton type                        |
| case_id        | int(11)     | Case id                              |
| patient_id     | int(11)     | Patient id                           |
| operation_id   | int(11)     | Operation id                         |

## Disease\_Data

| Field      | Type        | Definition     |
|------------|-------------|----------------|
| consult_ID | Varchar(50) | Primary Key    |
| Disease    | Int(10)     | Disease code   |
| Age        | Int(10)     | Patient age    |
| Gender     | Int(10)     | Patient gender |
| Region     | Varchar(50) | region         |
| City       | Varchar(50) | city           |

## Injury\_Data

| Field          | Type         | Definition            |
|----------------|--------------|-----------------------|
| case_ID        | Varchar(50)  | Primary Key           |
| Patient_id     | Int(11)      | Patient id            |
| Injury_date    | Int(11)      | Date of injury        |
| city           | Int(11)      | city                  |
| region         | Int(11)      | region                |
| mechanism      | Int(11)      | mechanism             |
| mortality      | Int(11)      | Whether dead or alive |
| Injury_details | Varchar(100) | Details of the injury |
| age            | Int(11)      | Patient age           |
| sex            | Char(2)      | Patient sex           |
| diagnosis      | Varchar(100) | diagnosis             |

## **Injury\_Mechanism**

| <b>Field</b>      | <b>Type</b>  | <b>Definition</b>  |
|-------------------|--------------|--------------------|
| identifier_id     | Int(11)      | Primary Key        |
| mechanism         | Varchar(50)  | Injury mechanism   |
| mechanism_keyword | Varchar(100) | Mechanism keywords |

## **Updates**

| <b>Field</b> | <b>Type</b> | <b>Definition</b>       |
|--------------|-------------|-------------------------|
| update_id    | Varchar(50) | Primary Key             |
| date         | Date        | Date of update          |
| time         | time        | time                    |
| tables       | Varchar(50) | Tables updated          |
| user         | Varchar(50) | User who did the update |

## **E. Technical Framework**

The Telehealth Knowledge Base will be a web-based system that follows the client-server architecture. The following shows the minimum configuration:

### **Hardware**

- 2GHz processor or faster
- 64mb video card or higher
- 256 MB of RAM or higher
- 10 GB available hard disk space or bigger

### **Software**

- Linux/Microsoft Windows XP/Vista/7
- Broadband /DSL/internet connection
- Google Chrome/Mozilla Firefox/ Internet Explorer
- JavaScript enabled
- XAMPP
- MySql 4 or a later version

- PHP 5

## V. Results

Figure 13 shows the homepage of Telehealth Knowledge Base. The system has three kinds of users – the system administrator, the NTHC employee/researcher and guest users. System administrators and NTCH employees can log-in to the system by clicking on the login link found on the right side of the system's navigation bar. Figure 14 shows the login form of the system.

**Figure 13:** Homepage of Telehealth Knowledge Base

**Figure 14:** Login Form of Telehealth Knowledge Base

When a registered user successfully logs in to the system, he/she will be redirected back to the homepage. This time, an additional Manage navigation tab is made available to the user. Figure 15 shows the homepage for logged-in users of the Telehealth Knowledge Base.

**Figure 15:** Homepage for Logged-in Users of Telehealth Knowledge Base

Hovering on the search link on the navigation bar will display a fly-out list of the different search functionalities the system is currently providing. This list includes

hospitals/health institutions and doctors for the guest users. Additional choices like immunization, nutrition, diseases, dental, injury and surgery reports are available for registered users. Figures 16 and 17 show the search options for guests and registered users, respectively.

**Figure 16:** Search options for guest users

**Figure 17:** Search options for registered users

Figure 18 shows the form for searching hospitals or health units. A user can search for a certain hospital, barangay clinic or rural health unit by choosing a region, city and type. They can also add a hospital name, facility name and quantity to make the query return a more specific result.

**Figure 18:** Search Health Units Form

Clicking on the search button will bring the user to the hospital results page (shown in Figure 19) where a list of hospitals matching his/her queries is shown. If the search result is still too big for the user, he/she can filter through the search result by inputting some keywords on the search box on the right hand side to of the table as seen on Figure 20. The user also has the option of sorting the table contents by clicking the table headers.

**Figure 19:** Hospital Results Page

**Figure 20:** Filter Hospital Results

A user also has the option to view the result via the adapted GIS module. Figure 21 shows the Map Representation of the hospital results.

### **Figure 21:** Map Representation of Hospital Results

Clicking on the markers on the map will display an info window with the hospital's address as preview information. Clicking on the link provided on the info window will bring the user to the hospital details page.

### **Figure 22:** Hospital Image, Hospital Details Page

### **Figure 23:** Hospital's Basic Information and List of Doctors, Hospital Details Page

### **Figure 24:** List of Hospital's Facilities, Hospital Details Page

Figures 22, 23 and 24 show the hospital details page. This page shows all the available information such as complete address, contact number, common names, list of doctors and their respective schedules, and list of facilities and their respective quantities for the hospital of choice. This page also provides an option to view the chosen hospital on the map, just like in Figure 20. Aside from the link in the info window of the map, a user can also go to this page by clicking on the hospital names in the search result. There is a filtering functionality on the tables so that users can filter through really big results. Sorting of the table contents is also available – the user just have to click on the header of the column to be sorted.

### **Figure 25:** Search Doctors Form

Figure 25 shows the form for searching doctors. A user has the option to search for a doctor in a given region or city, using the doctor's name, specialty and schedule. Clicking the search button results to a list of doctors and their respective contact number and specialty as shown in Figure 26.

### **Figure 26:** Doctors' Search Result

Toggling the plus icon on the left side of a doctor's name will display a table of the hospitals where they work and their respective schedules on each institution (Figure 27). This table will only include schedules that match the schedule user's query. Clicking on the doctor's name will redirect the user to a doctor's details page (Figure 28) wherein all the available information such as contact number, specialty and all schedules are displayed. The user can also view the hospitals where the chosen doctor work via the GIS. Again, the tables can be further filtered (Figure 29) and sorting of columns is available as well.

### **Figure 27:** A Table of Doctor's Schedules That Match the Search Query

### **Figure 28:** Doctor's Detail Page

### **Figure 29:** Filtered Doctor's Result

The system generates various statistical reports in different areas such as immunization, nutrition, disease, dental health and injury. All reports, except for the surgery ones, are location-based, drilled-down to provincial units. All of the location-based reports adhere to the following standards in presenting its data.

1. When a user decides to leave the region and city drop-downs to its default state, a nationwide report drilled-down on a per region basis is displayed. The graphical view of this kind of report displays a pie chart representing the percentages of each data group.

Below it is a horizontal bar graph that represents the breakdown of values for each region in the Philippines.

2. When a user chooses a region but decided to leave the city drop-down to its default state, a regional report drilled-down on a per city/province basis is displayed. The graphical view of this kind of report displays a pie chart representing the percentages of each data group. Below it is a horizontal bar graph that represents the breakdown of values for each city.
3. When a user chooses both a region and city from the drop-down choices on the search form, a report for that specific location is displayed. The graphical view is a pie chart representing the percentages of each data group.
4. A map representation that displays the frequency of each data group is available for the immunization, nutrition, disease, injury and dental health statistical reports. Higher values are represented by darker shades of colors and low values are represented by lighter shades of colors. Clicking an area in the map will trigger the visibility of an info window that shows the number of occurrence for that area.

All of the health reports, except for surgery reports, shown in the succeeding sections observe these standards.

**Figure 30:** Search Immunization Reports Form

Figure 30 shows the form for searching immunization reports. Users can generate three kinds of statistical immunization reports namely Fully-Immunized Child Report, Accomplishment Report per Immunization Schedule and Accomplishment per Vaccine given a region, a city/province and a time-span as input. All reports generated here follows the standards previously mentioned above. Figures 31 – 57 shows the immunization reports created by the system and their different representations.

**Figure 142:** Search Surgery Report Form

Aside from the location-based reports discussed above, surgery reports from the ISIS database are also included. Figure 142 shows the form for searching surgery records. Users can generate a surgery report grouped according to outcome, classification and operation type and time-span as input. Because the surgery data does not include any location information, it does not follow the report standards like the other reports. It is not drilled-down on a per location basis and the results are not viewed on the interactive map, only in tables and graph.

**Figure 149:** Compiled Reports Form

Figure 149 shows the compiled reports form. This form allows the user to generate all of the previously mentioned reports given region, city/province and time span. Reports are displayed under a tab for each category. They also follow the same format as the previously discussed reports; nationwide reports are created when no region or city is selected, regional ones when a region is selected and a report for a specific location is selected when both region and city fields are supplied. Figures 150, 151 and 152 show the compiled reports page for each scenario. Reports on this page can also be represented in graphs and maps.

**Figure 150:** Nationwide Compiled Reports Page

**Figure 151:** Regional Compiled Reports Page

### **Figure 152:** Compiled Reports Page for a Specific Location

A compilation reports for a certain location is also readily available when a user clicks on any location link on reports generated or by clicking the link provided in the info window of the map as seen in Figure 156. However, this does not include a time-span filter. The user has to go to the Compiled Reports page in order to generate compiled reports for a given time-period.

### **Figure 153** Info Window that provides link to the compilation report of a location.

### **Figure 154:** Update Data Warehouse Form

In order for the data warehouse to have valid data, it must be regularly updated by the system administrator. Figure 156 shows the update form for the data warehouse. Because updating the data warehouse usually takes time, an option to select just a subset of data for updating is available.

### **Figure 155:** Table of the Previous Updates Done By System Administrators

In order know up to when the records in the data warehouse are valid, the previous updates are tracked. Figure 155 shows the table of the previous updates done on the data warehouse, including the date and time it is updated, what tables were updated and who updated it. Only system administrators are allowed to update the data warehouse.

**Figure 156:** Add new user form

Figure 158 shows the add new user form. This is accessed via the Manage navigation tab on the navigation bar. Only system administrators are allowed to have access to this functionality.

**Figure 157:** List of Existing Users

Figure 157 shows a list of all the registered users of the Telehealth Knowledge Base. A delete and edit icons are available beside each user. Clicking the edit icon leads to the edit user information page shown in Figure 158. Clicking the delete icon deletes the user from the database and redirects the page back to the list of users with a prompt message on top as shown in Figure 159.

**Figure 159:** Update User Information Form

**Figure 160:** Manage Account Page after User Deletion

### **Figure 161: My Account Form**

Figure 161 shows the My Account Form. Both the admin and employee users have this. Employees, however, do not have any right to change their user types.

## **VI. Discussion**

The Telehealth Knowledge Base is a system for data mining and data visualization that uses data gathered from five separate databases namely Nearest Hospital Search Information System (NHSIS), Child Immunization Database System (CIDS), Nutrition Monitoring System (NMS), Community Health Information System (CHITS), Injury and Surgery Information System (ISIS). It implements the technique called Extract-Transform-Load (ETL) to manipulate the data and make it adhere to a consistent format – in this case, the location format of the existing GIS.

Data is first gathered from the different databases. The location data are the first priority for transformation because it has to observe the format that the existing Geographical Information System is using. Other fields that are transformed are the gender and birthday fields. For the injury data, the MOI (Mechanism of Injury) part of the string from the history field of the ISIS database is matched against a set of injury mechanisms.

Aside from hospitals and doctors' information, the system is only concerned in generating statistical reports. Because of that, only the data needed for creating these reports are gathered.

Patients' personal information such as names and addresses are not stored on the Telehealth Knowledge Base's database.

The transformed data is loaded to denormalized data marts on the system's database. While denormalization is considered bad and wasteful for Online Transactional Systems, it is ideal for Online Analytical Systems like the Telehealth Knowledge Base because it reduces a significant number of SQL JOIN which is considered beneficial for gathering reports from large systems. For example, instead of joining four tables to generate the disease reports, the system only has to send a simple SELECT query with WHERE conditions.

The ETL process is invoked whenever a system administrator does a manual update of the data warehouse. Thus, the data stored in the data warehouse is only valid up to the latest date and time of update.

The data warehouse presents the transformed data to the users using tables, graphs and interactive map. It uses a drill-down approach of data representation by breaking down each report to smaller components – e.g. the nationwide report is broken down into regions and the regional ones to provincial units. This is quite useful in analysing the data trend in a certain region or province.

The system also adapts the existing mapping functionality of the Telehealth Geographical Information System created by Jennifer Ong to provide geographical representations to reports. This is done by creating an xml file with the data of the area and passing it to the scripts of the GIS for parsing.

While the system offers various ways of reporting for better data visualization, the reports that it generates are dependent on the data of the source systems. If the source operational databases fail to provide true and correct data, the data warehouse will have ambiguous records.

## **VII. Conclusion**

The Telehealth Knowledge Base is a data warehouse integrated with an existing geographical information system called Telehealth Geographic Information System. Its main goal is to address the problem of disparate and scattered information by integrating data from different source systems. Data is made unified by the process called Extract-Transform-Load. Location information is made consistent with the location format of the adapted GIS. It uses MySQL's Full-Text-Search function for transforming data and denormalization to reduce query time in generating statistical reports.

The system combines different areas of health care and allows users to search for different kinds of information such as hospital and doctors' records, immunization, nutrition, diseases, dental health, injury and surgery reports. It presents different types of reports in tabular, graphical and geographical representations making it useful for analysing data trends and relationships.

The system is designed for the National Telehealth Center and includes the systems from their Knowledge Base Module namely Nearest Hospital Search Information System (NHSIS),

Child Immunization Database System (CIDS), Nutrition Monitoring System (NMS), Community Health Information System (CHITS), Injury and Surgery Information System (ISIS).

## **VIII. Recommendations**

At the moment, the system is limited to only five databases. More information must be added to the system to provide better data visualization and decisioning support. Addition of other relevant systems is highly recommended.

The system uses the drill-down approach of representing its data, nationwide reports are broken down into per region output and regional reports are broken down into provincial ones. It would be better if the system would allow data representation for smaller units of location such as municipalities and barangays. At the moment, this can't be done since the data in the source systems are limited to regional and provincial records.

Reports are limited to what can be generated from the data that the source systems could provide. Creating an additional query builder that would allow registered users to query the databases on the fly would be a good addition to the system. A tool that would allow a registered

user to create and save stored procedures for generating a certain kind of report will be a good option to have.

At the moment, the data warehouse is updated using the full-refresh method – old data is deleted from the database and then a new set of data is inserted every night or when a system administrator invokes a manual update. It would be more useful if this process can be improved to just capture the updates made on the source systems instead of extracting and transforming data for every update. This would also be beneficial, as it would provide means to maintain and track historical data. Setting-up a cron job for automatic update is recommended.

The adapted GIS module of this system uses the Google Maps API. Because of this, the mapping functionality is only limited to what it can provide and thus have to agree to its terms and conditions. Also, because the API retrieves geocode addresses from Google, the map cannot be used offline and loads slowly when the internet connection is slow. Another free-source mapping API that would allow users to use the map offline would be a great improvement for the system.

```

The Telehealth Knowledge Base is a data warehouse integrated with an existing geographical information system called Telehealth Geographic Information System. Its main goal is to address the problem of disparate and scattered information by integrating data from different source systems. It is designed for the National Telehealth Center (NThC) of University of the Philippines Manila which enhances access to health care through information and communications technology.

</p>

<p>

The system currently mines data and generate reports from the following database: <br>

- <a href="">Nearest Hospital Search Information System (NHSIS)</a></li>
- <a href="">Child Immunization Database System (CIDS)</a></li>
- <a href="">Community Nutrition Management System (CNMS)</a></li>
- <a href="">Community Health Information Tracking System (CHITS)</a></li>
- <a href="">Integrated Surgery Information System (ISIS)</a></li>

</ul>

</p>

## XI. Acknowledgements

Without any doubt, the years that I've stayed in UP-Manila are far by the hardest in my life. I am so glad that after all the hurdles and tears that I experienced, I never gave up and is now rewarded of writing my acknowledgement page. Let me use this little space to give gratitude to all of the people who helped me in more ways than they would ever know about.

First of all, my deepest gratitude goes to my adviser, Ma'am Ma. Shiela Magboo. Without the topic that you gave me, I am pretty sure I wouldn't be writing this acknowledgement page today. Thank you so much because you never gave up on me even though I'm probably one of your most annoying advisee. Hehe. Thank you for giving me the chance to defend my SP and graduate this semester. I really wouldn't have done this without you.

Thank you Sir Chua, Sir Solano, Doc Magboo and Ma'am Perl because you didn't reject my topic even though I'm pretty sure all of you are thinking that it is too easy for an SP. And thank you Sir Co for the Cornetto. □

To my college friends, Tina, Jan, Pat, Rov and Ian. Thank you for all the bonding moments that we shared. I miss you all and I hope to have more bonding moments with you soon.

Thank you Cambridge University Press for giving me a job even though I'm still an undergrad. My deepest thanks goes to Boss Ronnie, Boss Edong, Miss Kat, Philippe and JR. I wouldn't have worked so hard on finishing this SP if you didn't accept me as one of your JSEs. To my teammates, Ariel and SaG. Thank you for enduring my lack of knowledge on almost everything. Haha. To my boss Nik Derewianka, thank you because you still haven't terminated me even though I'm almost always absent because of this thesis. :P

To my lunch buddies in CUP-Manila, Aura, Eulah, JM, Mik, JC and Niel. Thank you so much for pressuring me to finish my SP. I wouldn't have done this without the bullying (Ehem, Niel. Please don't forget about our deal) and words of encouragement. Special thanks to Mami JJ for helping me on importing my databases and for encouraging me to finish this project. You are the epitome of kindness. □

And of course, to my family. To Nanay, Tatay, Ian and Ace. Thank you so much for all the support and understanding that you have given me. I know that I have disappointed you a lot of times already but you gave it your best to understand all of my failures and still continued on supporting me. I love you all and this SP is for you.

And to you, Lord. Thank you so much. I know I don't really deserve any of your kindness and yet you still continue to shower me with your blessings. Words are not enough to express my gratitude.

To all of the graduates this year, congratulations to us. □
